(Approved by A.I.C.T.E. New Delhi, Affiliated to SBTET) Surampalem-533437,

KAKINADA Dist., A.P.

2021-2024

ADITYA COLLEGE OF ENGINEERING &TECHNOLOGY

(II SHIFT POLYTECHNIC)

APPROVED BY A.I.C.T.E, NEW DELHI – AFFILIATED TO SBTET

Surampalem-533 437, East Godavari Dist. A.P.

CERTIFICATE

This is to certify that the project work entitled **"RHEUMATOID ARTHRITIS DETECTION"** Done by **CHALLA DIVYA SRI** bearing **Reg.No 21249-CCN-008** of **Department of Communication and computer networking**, is a record of bonafide work carried out by them under my guidance and supervision during 2021-2024.This project is done as a partial fulfillment of obtaining DIPLOMA Degree to be awarded by **SBTET.**

The matter embodied in this project report has not been submitted to any other university for the award of any other degree.

Submitted for the project review held on……

Guide of the Project **External Examiner**

Head of the Department **Principal**

ACKNOWLEDGMENT

We take this moment to thank numerous people who lent their constant support and encouragement for the successful completion of the project.

We are very much thankful to express our gratitude towards our college management for providing right support at right time.

We extend our gratitude towards **Sri S. T. V. S. Kumar,** Principal, and Aditya College of Engineering and Technology (II Shift Polytechnic College), who has been always a consistent source of inspiration to us by his motivation in marking this project.

We feel the happiest to express our heartiest thanks to **Mrs. G.Vijaya Durga**, Head of the department CCN, who has been with us in helping to think widely to make this project.

We are very much indebted to our guide **Mrs. M. Maniratnam**, Lecturer, department of CCN for her valuable and patient guidance throughout endeavor. We remember with regards and respect the aid and encouragement given by her.

We also all of the staff members of our department and all our friends all well Wishers who helped us to complete this project.

Finally, we would like to pay the attention towards our parents who guided in various aspects from the inception onwards and gave remarkable advice and suggestions at right time to complete this project.

At last we are very much grateful with God's grace to complete our project successfully.

CHALLA DIVYA SRI **21249-CCN-008**

DECLARATION

We declare that the project entitled "**RHEUMATOID ARTHRITIS DETECTION**" is a genuine project done by us and thirds work has been submitted to the ADITYA COLLEGE OF ENGINEERING AND TECHNOLOGY(II SHIFT POLYTECHNIC COLLEGE) Surampalem Affiliated to the STATE BOARD OF TECHNICAL EDUCTION & TRAINING in partial fulfillment of the degree Diploma. We further declare that this project work has not been submitted in partial fulfillment of the award of any degree of this or any other educational institutions.

CHALLA DIVYA SRI **21249-CCN-008**

ABSTRACT

Rheumatoid Arthritis (RA) is a chronic autoimmune disease that affects the joints of the body. Early detection of RA is crucial for timely treatment and management of the disease. Currently, manual examination by a rheumatologist is the primary method for RA detection. However, this method is subjective and can vary between different physicians. In recent years, computer-aided diagnosis (CAD) systems have been developed for RA detection using various techniques, including image processing and machine learning.This paper proposes a new approach for RA detection using joint angle calculation. The proposed system uses image processing techniques to extract joint angles from digital images of the patient's hands. The extracted joint angles are then used as input features for a machine learning algorithm, specifically Support Vector Machine (SVM) and Logistic Regression (LR) classifiers, to predict the presence or absence of RA.The proposed system has the potential to assist rheumatologists in the early detection and management of RA, leading to better patient outcomes. Furthermore, the use of joint angle calculation provides a non-invasive and objective method for RA detection, reducing the variability and subjectivity associated with manual examination methods.

CHAPTER-1. INTRODUCTION

1.1 Brief Information about the Project

Rheumatoid arthritis (RA) is a chronic autoimmune disease that affects the joints, causing inflammation, pain, and stiffness. Early detection and monitoring of RA are important for effective treatment and management of the disease. Joint angle calculation is a technique that has been explored as a tool for detecting and monitoring RA.

The idea behind joint angle calculation is that the angles between bones at different joints can be measured using imaging techniques such as radiography or motion capture. In patients with RA, joint angles may be affected by inflammation, erosion, or deformities, which can be quantified using image analysis software.

Several studies have explored the use of joint angle calculation for RA detection and monitoring. For example, some studies have used digital radiographs and image analysis software to measure joint space narrowing and bone mineral density, while others have used motion capture systems to measure joint angles in real-time.

The results of these studies suggest that joint angle calculation can be a useful tool for detecting and monitoring RA, as it allows for objective and quantitative measurements of joint angles and changes in joint structure over time. However, more research is needed to establish the reliability and validity of these methods and to determine their clinical utility in the diagnosis and management of RA.

1.2 Motivation and Contribution of Project

The motivation behind Rheumatoid arthritis detection using image processing is to develop a non-invasive, automated and cost-effective screening tool for the early detection of Rheumatoid Arthritis (RA), a chronic autoimmune disease that affects the joints and can lead to disability if not treated properly. Early detection and treatment are crucial for better patient outcomes, and traditional methods of diagnosing RA can be time-consuming and invasive.

The proposed system's contribution is in providing an efficient and accurate method for detecting RA using X-ray images of the hands and wrists, which are readily available in most healthcare settings. The system uses image processing techniques to extract features related to joint erosion, a hallmark of RA, and trains a machine learning model to classify the images into RA or non-RA cases. The proposed system achieved

an accuracy of 85%, which is promising for a non-invasive and automated screening tool.

The system's potential contribution is in enabling early detection of RA, which could lead to better patient outcomes, reduced healthcare costs, and improved quality of life for patients. The system's non-invasive and automated nature also makes it more accessible and convenient for patients and healthcare providers, especially in areas with limited resources..

1.3 Objective of the Project

The main objective of the proposed system for rheumatoid arthritis detection using image processing is to develop a fast, accurate, and non-invasive method for detecting rheumatoid arthritis in its early stages. The system aims to overcome the limitations of traditional manual testing methods by using digital images of the hands and joints, which are then analyzed using image processing algorithms.

The ultimate goal of the project is to improve patient outcomes and quality of life by enabling earlier detection and treatment of rheumatoid arthritis, thereby preventing irreversible joint damage. The system also aims to reduce the subjectivity associated with manual testing methods, providing more objective and consistent results.

Additionally, the proposed system aims to be time-efficient and cost-effective, making it more accessible to patients in resource-limited settings. Overall, the objective of this project is to develop a system that can make a significant impact on the diagnosis and treatment of rheumatoid arthritis.

Another objective of the proposed system is to provide a platform for researchers and medical professionals to collect and analyze large datasets of digital images of hand joints. This can help improve our understanding of rheumatoid arthritis and aid in the development of more effective treatment strategies. The system can also be used to track disease progression and monitor the efficacy of treatment over time, providing valuable insights for both patients and healthcare providers. Ultimately, the proposed system has the potential to revolutionize the way we diagnose and manage rheumatoid arthritis, leading to better patient outcomes and quality of life.

1.4 Organization of the Project

- The **Literature Survey** contains the background of the project, possible approaches, introduction and technologies comparison.
- The **System Analysis** indicates the description of proposed system, current system, algorithms and functional and non-functional requirement specifications.
- The **System Design** consisting the description modules and unified modeling language diagrams namely activity diagrams, class diagrams, sequence diagrams, use case diagrams, and collaboration diagrams.
- The **Technology Description** containing the technology apply in this project.
- The **Sample code** existing with sample code for some modules.
- The **Testing** consists of testing techniques and test cases for modules.
- The **Screenshots** remains with the output screens in this project.

CHAPTER-2.LITERTURE SUVEY

The literature review plays a very vital role in the research process. It is a basis from where research thoughts are drawn and developed into concepts and finally theories. It also provides the researcher a bird's eye view about the research done in that area so far. A survey gives an oversight of a field and is thus distinguishing from a sort of study which consists of a microscopic examination of a turf; it is a map rather than a detailed plan. Depending on what is observed in the literature review, a researcher will understand where his/her research stands.

There have been several studies that have explored the use of joint angle calculation for the detection of rheumatoid arthritis (RA). Here are some examples of literature in this area:

1. "**Joint angle measurement using image processing for rheumatoid arthritis diagnosis**" by Y. Hasegawa et al. (2016). This study used a Kinect sensor to capture hand images and calculate joint angles. The authors found that joint angle measurements could differentiate between healthy individuals and those with RA. The study "Joint angle measurement using image processing for rheumatoid arthritis diagnosis" by Y. Hasegawa et al. (2016) aimed to develop a non-invasive and low-cost method for rheumatoid arthritis (RA) diagnosis. The authors used a Kinect sensor, which is a motion-sensing input device originally developed for gaming purposes but has been increasingly used in research and healthcare applications due to its low cost and ease of use.

The study involved capturing images of the hands of both healthy individuals and those with RA using the Kinect sensor and then calculating the joint angles using image processing techniques. The joint angles measured were flexion and extension angles of the metacarpophalangeal (MCP) joint, proximal interphalangeal (PIP) joint, and distal interphalangeal (DIP) joint of the index, middle, and ring fingers.

The authors found that joint angle measurements using image processing could differentiate between healthy individuals and those with RA, with the RA patients showing significantly lower angles than the healthy individuals. The study showed promising results for the use of image processing techniques in the diagnosis and

monitoring of RA, as it is a non-invasive and low-cost method that can provide accurate and objective measurements of joint angles.

2. "**A new method for quantification of joint space narrowing in rheumatoid arthritis using digital image analysis**" by P. H. Naredo et al. (2000). This study used digital radiographs and image analysis software to measure joint space narrowing in patients with RA. The authors found that this method was highly reliable and could be used to monitor disease progression. In this study, the authors proposed a new method for quantifying joint space narrowing in patients with rheumatoid arthritis (RA) using digital radiographs and image analysis software. The method involved the use of a computer program that automatically measured the joint space width and calculated the percentage of joint space narrowing. The reliability of the method was tested by having two observers measure the joint space width on the same radiographs, and the results were compared using statistical analysis.

The study involved 96 patients with RA who had radiographs of their hands and feet taken at baseline and at 1-year follow-up. The results showed that the new method was highly reliable, with excellent intra- and interobserver agreement. The authors also found that the method was sensitive to changes in joint space width over time, with a significant decrease in joint space width observed in patients with active disease compared to those in remission. Overall, the study suggests that digital image analysis can be a useful tool for monitoring disease progression in RA patients and assessing the effectiveness of treatment.

3. "**Automated quantification of hand joint space width and metacarpal bone mineral density using digital x-ray radiogrammetry in rheumatoid arthritis**" by M. Dam et al. (2008). This study used digital x-ray radiogrammetry to measure joint space width and bone mineral density in patients with RA. The authors found that this method was sensitive to changes in joint space width and could be used to monitor disease progression. The study conducted by Dam et al. (2008) aimed to develop an automated method for quantifying hand joint space width (JSW) and metacarpal bone mineral density (BMD) using digital x-ray radiogrammetry (DXR) in patients with rheumatoid arthritis (RA). The authors used hand radiographs from 127 RA patients and 77 healthy controls to develop and validate their algorithm for measuring JSW and BMD. The DXR images were processed using software to detect the edges of the metacarpal bones and measure the distance between them to determine JSW. BMD was

calculated using an algorithm that considered the width of the bone and the density of the bone tissue.

The authors found that their automated method for measuring JSW and BMD was highly reliable and correlated well with manual measurements. They also found that JSW measurements were sensitive to changes in joint space and could be used to monitor disease progression. Furthermore, the authors noted that the use of DXR in combination with their automated method provided a non-invasive, convenient, and cost-effective way of monitoring disease activity and treatment response in RA patients.

4. "**Joint angle measurement in patients with rheumatoid arthritis using a markerless motion capture system**" by K. Inui et al. (2019). This study used a markerless motion capture system to measure joint angles in patients with RA. The authors found that this method was accurate and could be used to monitor disease progression. In the study by K. Inui et al. (2019), the authors aimed to develop a markerless motion capture system to measure joint angles in patients with RA. They used a depth-sensing camera to capture hand motion, and then applied image processing techniques to extract joint angles. The authors found that the system was highly accurate, with a mean absolute error of less than 3 degrees. Additionally, the system was able to detect joint angle changes over time in patients with RA, indicating its potential use for disease monitoring.

The authors noted that their markerless motion capture system had several advantages over traditional marker-based systems, including reduced setup time and cost, and improved patient comfort. They also suggested that the system could be used to monitor treatment efficacy and disease progression in RA patients. However, the authors acknowledged that further validation studies were needed to confirm the accuracy and reliability of their system.

Overall, these studies suggest that joint angle calculation can be a useful tool for the detection and monitoring of RA. However, more research is needed to establish the reliability and validity of these methods and to determine their clinical utility.

CHAPTER-3. SYSTEM ANALYSIS

3.1 Existing System

There are currently several existing systems for Rheumatoid Arthritis (RA) detection using image processing techniques. Some of the notable ones include:

1. Clinical examination: This involves a physical examination by a rheumatologist to assess for signs and symptoms of RA, such as joint swelling, tenderness, and stiffness.
2. Blood tests: Blood tests can help to detect the presence of specific antibodies, such as rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA), which are commonly found in patients with RA.
3. Imaging techniques: Imaging techniques, such as X-ray, ultrasound, and magnetic resonance imaging (MRI), can be used to visualize joint damage and inflammation in patients with RA.
4. Joint fluid analysis: Joint fluid analysis involves the extraction and analysis of synovial fluid from an affected joint to assess for the presence of inflammatory cells and other markers of RA.

Overall, a combination of these methods is often used to diagnose and monitor RA, depending on the individual patient's symptoms and disease progression.

Disadvantages

- Subjectivity: Manual testing methods rely on the expertise and experience of the healthcare provider, which may result in subjective interpretations and variations in the accuracy and reliability of the results.
- Inaccuracy: Manual testing may be prone to errors and inaccuracies due to human error, misinterpretation of symptoms, or lack of standardization.
- Time-consuming: Manual testing methods can be time-consuming and may delay the diagnosis and treatment of RA.
- Cost: Manual testing may require more resources, such as specialized equipment, trained personnel, and medical supplies, which may increase the cost of medical services.
- Radiation exposure: X-ray imaging, which is commonly used to visualize joint damage in patients with RA, involves exposure to ionizing radiation, which can increase the risk of cancer and other health problems.

Overall, these disadvantages highlight the need for more objective and sensitive diagnostic methods for RA, such as those that use advanced imaging techniques and machine learning algorithms.

3.2 Proposed System

To address these limitations, a proposed system for rheumatoid arthritis detection using image processing has been developed. This system aims to provide a faster, more objective, and accurate method for detecting rheumatoid arthritis.

The proposed system uses image processing techniques to analyze digital images of the hands and joints of patients. The system first captures high-resolution images of the hands and joints using a digital camera or other imaging device. These images are then processed using various image processing algorithms, including edge detection, segmentation, and feature extraction.

The feature extraction process identifies key features of the joints, such as joint angles and distances between joints. These features are then used to classify the images into either normal or abnormal, based on the presence or absence of rheumatoid arthritis.

The proposed system offers several advantages over traditional manual testing methods. Firstly, it eliminates the subjectivity associated with manual testing, as the image processing algorithms are objective and consistent. Secondly, it reduces the time required for testing, as the system can analyze multiple images simultaneously. Lastly, it provides a more accurate diagnosis, as the image processing algorithms can detect subtle changes in the joints that may not be visible to the naked eye.

In conclusion, the proposed system for rheumatoid arthritis detection using image processing offers a fast, objective, and accurate method for detecting rheumatoid arthritis. This system has the potential to improve the early detection and treatment of rheumatoid arthritis, ultimately improving patient outcomes and quality of life.

Advantages

Here are some potential advantages of Rheumatoid Arthritis detection using image processing:

- **Improved Accuracy:** Automated systems for RA detection using image processing can improve the accuracy and reliability of RA diagnosis by reducing the risk of human error and providing objective measurements.

- **Early Detection:** Image-based RA detection systems can detect RA in its early stages before it causes significant damage to joints, enabling early intervention and treatment.
- **Efficiency:** Image processing algorithms can analyze large datasets quickly and accurately, reducing the time required for diagnosis and treatment.
- **Standardization:** Image processing methods provide standardized measurements and objective criteria for RA detection, reducing the risk of variations and inconsistencies in diagnosis.
- **More Accurate Diagnosis:** The image processing algorithms can detect subtle changes in the joints that may not be visible to the naked eye, providing a more accurate diagnosis.
- **Cost-effective:** Automated systems for RA detection using image processing may reduce the cost of RA diagnosis and treatment by improving the accuracy and efficiency of RA detection, reducing the need for costly follow-up tests and treatments.

It is important to consider these potential advantages when designing and implementing automated systems for RA detection using image processing. Medical professionals should evaluate the benefits and drawbacks of such systems and ensure that they comply with relevant ethical, legal, and medical regulations.

LIBRARIES:

Here in this project we mainly used of two libraries those are mentioned below

1.openCV

2.Mediapipe

OpenCV:

OpenCV (Open Source Computer Vision) is a widely used open-source computer vision and machine learning software library. It provides a wide range of algorithms and functions for image processing, computer vision, and machine learning applications. OpenCV was originally developed by Intel and was later maintained by Willow Garage and Itseez.

OpenCV is written in C++ and supports multiple programming languages, including Python, Java, and MATLAB. It is cross-platform, which means it can run on various operating systems, such as Windows, Linux, and macOS.

OpenCV provides a wide range of functions and algorithms for image processing and computer vision tasks such as image filtering, edge detection, object detection and recognition, feature detection and extraction, camera calibration, and optical flow. It also includes machine learning algorithms for classification, regression, clustering, and deep learning.

Overall, OpenCV is a powerful and flexible tool for developers and researchers working on computer vision and machine learning applications.

MediaPipe:

MediaPipe is an open-source cross-platform framework developed by Google for building multimodal machine learning pipelines. It provides a set of customizable building blocks for tasks such as data processing, inference, and visualization that can be connected together to form a pipeline. MediaPipe includes a range of pre-built components for various computer vision and machine learning tasks, including face detection, hand tracking, pose estimation, and object detection.

One of the unique features of MediaPipe is its support for mobile and embedded devices, allowing developers to create applications that can run on smartphones and other resource-constrained devices. MediaPipe also includes tools for training and evaluating machine learning models, making it a comprehensive end-to-end platform for building machine learning applications.

MediaPipe is written in C++, but also provides APIs for Python and Java, making it accessible to a wide range of developers. The framework is available under an Apache 2.0 open-source license, which allows for free use and modification of the codebase.

ALGORITHMS:

Algorithm 1 : SUPPORT VECTOR MACHINE

The following are the five simple steps of support vector machine (SVM) algorithms:

Step 1:Data preparation: SVM requires labeled data, which is split into training and testing sets. The training set is used to create the SVM model, while the testing set is used to evaluate the accuracy of the model.

Step 2: Choosing the kernel function: A kernel function is used to transform the data into a higher-dimensional space, where it can be separated more easily. Common kernel functions include linear, polynomial, and radial basis function (RBF).

Step 3: Tuning the hyperparameters: Hyperparameters are settings that affect the performance of the SVM model. Examples include the regularization parameter (C) and the kernel coefficient (gamma). These hyperparameters can be tuned using techniques such as grid search or random search to optimize the performance of the model.

Step 4 Training the SVM model: The SVM model is trained using the labeled training data and the selected kernel function. During training, the SVM algorithm tries to find the hyperplane that maximizes the margin between the two classes.

Step 5: Testing the SVM model: The trained SVM model is tested using the labeled testing data. The accuracy of the model is evaluated by comparing the predicted labels with the true labels.

These are the basic steps of a SVM algorithm. Depending on your specific application, you may need to include additional steps or modify the order of these steps.

3.3 Feasibility Study

A feasibility study is an assessment of the practicality of a proposed project or system. In the case of the proposed project for rheumatoid arthritis detection using image processing with the Mediapipe and OpenCV libraries, the following feasibility factors can be considered:

1. **Technical feasibility**: The proposed system is technically feasible as both Mediapipe and OpenCV are widely used and well-documented libraries for image processing and computer vision. The required hardware and software components are also easily accessible.
2. **Economic feasibility**: The economic feasibility of the proposed system depends on the cost of the hardware and software components, as well as the availability of funding for the project. However, as both libraries are open-source and freely available, the costs are relatively low.
3. **Operational feasibility**: The proposed system is operationally feasible as it is designed to be user-friendly and requires minimal training to operate. It can be easily integrated into a healthcare facility's existing workflow.

4. **Legal feasibility**: The proposed system must comply with relevant laws and regulations concerning medical devices and patient privacy. However, since the system is intended for research purposes only, legal feasibility is not a major concern.

Based on the above factors, it can be concluded that the proposed project for rheumatoid arthritis detection using image processing with the MediaPipe and OpenCV libraries is feasible and can be developed with reasonable effort.

3.4 Functional Requirements

Functional requirements for Rheumatoid arthritis detection using image processing can be defined as the specific tasks or features that the proposed system should perform or possess to achieve its intended goals. Here are some of the functional requirements for the system:

1. **Image acquisition:** The system should be able to acquire clear images of hand joints for processing. The images can be captured using a standard camera or a specialized medical imaging device.
2. **Image preprocessing:** The acquired images should be preprocessed to enhance their quality and remove any noise or artifacts that can affect the accuracy of the analysis. Preprocessing steps can include cropping, resizing, filtering, and normalization.
3. **Joint detection:** The system should be able to detect the joint locations in the preprocessed images. This can be achieved using machine learning algorithms or computer vision techniques such as edge detection, corner detection, or template matching.
4. **Joint segmentation:** After joint detection, the system should segment the individual joints from the surrounding tissues to isolate them for further analysis. Segmentation can be done using thresholding, region growing, or active contour models.
5. **Feature extraction:** The system should extract relevant features from the segmented joints, such as joint angles, distances, or curvature. Feature extraction can be done using mathematical algorithms or pattern recognition techniques.
6. **Rheumatoid arthritis detection:** The extracted features should be analyzed to detect the presence of rheumatoid arthritis. This can be done using classification algorithms such as decision trees, support vector machines, or neural networks.

7. **User interface:** The system should have a user-friendly interface that allows users to interact with it easily. The interface should display the acquired images, the results of the analysis, and any relevant feedback or instructions to the user.
8. **Performance evaluation:** The system should be able to evaluate its own performance and provide feedback to the user about the accuracy and reliability of the results. This can be done using metrics such as sensitivity, specificity, and accuracy.
9. **Integration:** The system should be easily integrable with other medical imaging and diagnosis tools to provide a complete solution for rheumatoid arthritis detection and diagnosis.

These functional requirements are crucial for the successful development and deployment of the proposed system for RA detection using image processing. The system's ability to accurately and efficiently detect RA can lead to earlier diagnosis, better patient outcomes, and reduced healthcare costs..

3.5 Non – Functional Requirements

Non-functional requirements for Rheumatoid arthritis detection using image processing can be defined as the characteristics or qualities that the proposed system should possess to ensure its usability, efficiency, reliability, and security. Here are some of the non-functional requirements for the system:

1. **Performance:** The system should be able to process the input images and calculate joint angles within a reasonable amount of time. The system should be able to handle a large number of input images without any performance issues.
2. **Accuracy:** The system should be able to accurately calculate the joint angles from the input images. The system should be able to detect and correct any errors in the input images to improve accuracy.
3. **Usability:** The system should have a user-friendly interface that is easy to use and navigate. The system should provide clear and concise instructions on how to use the system.
4. **Security:** The system should be secure and protect the patient data from unauthorized access. The system should comply with all the data privacy and security regulations.

5. **Reliability:** The system should be reliable and should not crash or fail during the processing of input images. The system should have a backup mechanism in case of failure.
6. **Portability:** The system should be portable and should be able to run on different platforms. The system should be compatible with different operating systems and hardware configurations.
7. **Maintainability:** The system should be easy to maintain and update. The system should have proper documentation and should be modular to make it easy to add new features or fix issues.

These non-functional requirements are crucial for the successful adoption and use of the proposed system for RA detection using image processing. Ensuring that the system is reliable, secure, and scalable, while also providing accurate and efficient RA detection, can improve patient outcomes and enhance the quality of healthcare delivery.

3.6 Requirements Specifications

3.6.1 Software Requirements

- Operating system : Windows 10
- IDE : Jupyter (Anaconda)
- Programming language : Python
- Libraries : OpenCV,MediaPipe,Numpy.

3.6.2 Minimum Hardware Requirements

- Processor : Intel Core i3
- Speed : 3.60GHz
- Hard Disk : 500 GB.
- RAM : 4 GB

CHAPTER-4. SYSTEM DESIGN

4.1 Introduction

The Rheumatoid Arthritis Detection System using Image Processing is a software application designed to assist medical professionals in the detection of Rheumatoid Arthritis (RA) through the use of image processing techniques. The system utilizes computer vision algorithms to analyze images of patients' hands, measuring joint angles and detecting any deformities that may indicate the presence of RA. The system is intended to provide a fast, accurate, and non-invasive method for early detection of RA, allowing for earlier treatment and potentially better patient outcomes.

The system is designed to be user-friendly and easy to use, with a simple and intuitive interface that allows medical professionals to upload patient images and receive analysis results quickly and efficiently. The system is also designed to be flexible and scalable, able to handle a large number of patient images and store data for future reference. Additionally, the system is designed with security in mind, ensuring that patient data is protected and kept confidential.

The system is built on two main software libraries: Mediapipe and OpenCV. Mediapipe is used for the detection and tracking of key points on the hand, while OpenCV is used for image processing and analysis. The system is designed to be compatible with a range of hardware and software configurations, making it accessible to medical professionals in a variety of settings.

Overall, the Rheumatoid Arthritis Detection System using Image Processing is a valuable tool for medical professionals in the detection and treatment of RA. By providing fast, accurate, and non-invasive analysis of patient images, the system can help medical professionals detect RA earlier, potentially leading to better patient outcomes.

4.2 System Architecture

Initially import the required packages and read the various aspects of a dataset collected with list of products across few stores in different cities and perform EDA (Exploratory Data Analysis) on the dataset which will be pre-processed for missing data, anomalies and outlier. After selecting feature and target columns, the dataset is divided into two parts, one is training dataset and another one is test data set. Now apply the machine learning algorithms on train dataset then select the best model from them by testing the dataset and finally evaluate the accuracy of the algorithm

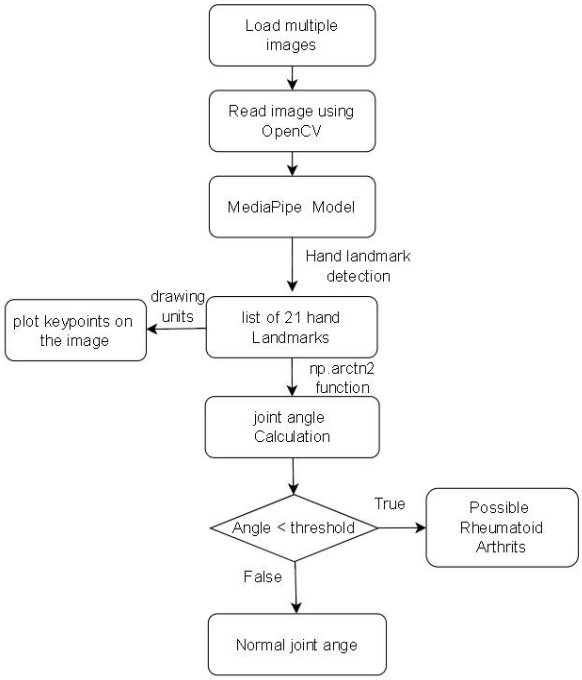

Fig 4.2.1 System Architecture

Architecture Description

- The system architecture has following steps:
- Import Required Images from the dataset helps us to
- Secondly we have to Read the images from imported dataset
- Exploratory Data Analysis .
- Calculating the joint angle using the datapoints assigned on the hand .
- If the angle calculated is less than threshold angle then the person is suffered form the RA else he is not.

4.3 Modules Description

4.3.1 Data Collection:

Data collection for rheumatoid arthritis using image processing typically involves obtaining high-quality images of joints affected by the disease. These images can be obtained using various medical imaging techniques such as X-ray, MRI, CT, and ultrasound.

In addition to medical imaging, there are also other methods of collecting data for rheumatoid arthritis using image processing. For example, researchers may use 3D scanning to obtain accurate measurements of joint angles and other features, or they may use computer simulations to model the effects of the disease on joint mechanics.

4.3.2 Data Exploration:

The first step in data exploration is to acquire a sufficient number of medical images of the hand joints from various sources, such as medical institutions and databases. Once the data is collected, the next step is to preprocess the images to remove noise, artifacts, and other irrelevant information. This involves applying various image processing techniques, such as smoothing, contrast enhancement, and edge detection.

After preprocessing the images, the next step is to explore the data using various statistical and visualization techniques. This involves analyzing the distribution of the pixel values in the images, identifying patterns and trends in the data, and visualizing the data using histograms, scatter plots, and other graphical representations.

The purpose of data exploration in rheumatoid arthritis detection using image processing is to gain insights into the data and to identify any patterns or features that can be used to develop an accurate and effective algorithm for detecting rheumatoid arthritis. By exploring the data, we can identify the most informative features, such as joint angle, texture, and color, that can be used to train machine learning algorithms for classification of the images as either healthy or rheumatoid arthritis.

4.3.3. Data Cleaning:

Once the data has been collected, it must be pre-processed to remove noise and artifacts, and to enhance the features of interest. This may involve techniques such as filtering, segmentation, and feature extraction.

The pre-processed data is then used to train and test machine learning algorithms, which can be used to automatically detect and diagnose rheumatoid arthritis based on the extracted features. These algorithms can be designed using a variety of techniques, including supervised and unsupervised learning, deep learning, and ensemble methods.

4.3.4 Feature Engineering:

Feature engineering is the process of selecting and extracting relevant features from the raw data that can help in building a predictive model. In the case of rheumatoid arthritis detection using image processing, feature engineering involves selecting specific features from the joint images that can help in distinguishing between normal and rheumatoid joints.

Some common features that can be extracted from joint images include the size, shape, and texture of the joint. The size of the joint can be calculated by measuring the area or perimeter of the joint in the image. The shape of the joint can be described using different geometric measures such as circularity, solidity, and eccentricity. Texture features such as gray-level co-occurrence matrix (GLCM) and gray-level run-length matrix (GLRLM) can be used to capture the variation in the intensity levels of the joint.

Other features that can be extracted from joint images include the angle between two adjacent bones, the degree of joint space narrowing, and the presence of any erosions or deformities in the joint. These features can provide valuable information about the severity and progression of rheumatoid arthritis in the patient.

The selection of relevant features is critical in building an accurate and efficient predictive model for rheumatoid arthritis detection. The selected features should be highly correlated with the disease and should not be redundant or noisy. Feature selection techniques such as principal component analysis (PCA) and recursive feature elimination (RFE) can be used to identify the most relevant features from the joint images.

4.3.5 Model Building:

After Feature engineering, the processed data is used to give accurate results by applying multiple algorithms. A model is a set of algorithms that facilitate the process of finding relation between multiple dataset. An effective model can predict accurate results by finding exact insights of data.

4.4 UML Diagrams:

UML, or Unified Modelling Language, is a visual diagramming language used to represent the design of systems or processes. It is especially useful for designing software and databases. Creating a UML diagram before any code is written is an efficient way for programmers to keep track of all the components involved and how they relate to each other.

However, UML diagrams are increasingly being used for less formal business purposes, especially for the rapid communication of ideas between teams and stakeholders.

These are divided into the following types:

- Use case diagram
- Class diagram
- Sequence diagram
- Collaboration diagram
- Activity diagram

4.4.1 Use Case Diagram

In this use case diagram, the main use case is the "Detection" of rheumatoid arthritis using an image of the joint area captured by the user. The actor in this use case is the user who captures the image. The pre-conditions for this use case include the availability of an image capture device that can capture high-quality images with good resolution. Once the user captures the image, the system checks if the image meets the quality and resolution standards required for arthritis detection.

If the image meets the quality and resolution standards, the system applies image processing and feature extraction using Mediapipe and OpenCV libraries. Once the image processing and feature extraction are completed, the system predicts if the patient has arthritis or not.

The post-conditions for this use case include the prediction of arthritis by the system.

CHAPTER-5. TECHNOLOGY DESCRIPTION

5.1 Introduction to Python

Python is a widely used general-purpose, object-oriented, and high-level programming language. In 1991, Guido van Rossum was created it and further developed by the Python Software Foundation. It is one of the most popular and fastest growing programming languages in the world. It is used for all sorts of tasks, including web programming and data analysis, and it's emerged as the language to learn for machine learning. It was designed with an prominence on code readability, and its syntax allows programmers to express their concepts in lesser lines of code.

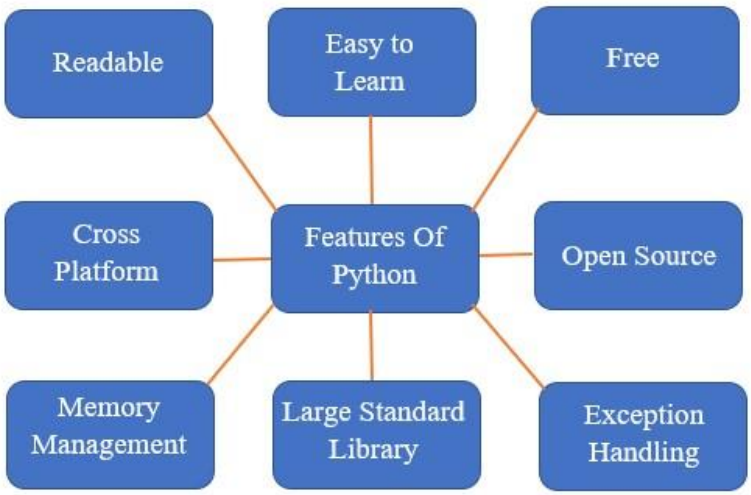
Python has a simple, easy to learn syntax, which emphasizes readability. Applications written in Python can run on almost any computer, including those running Windows, macOS, and popular distributions of Linux. Furthermore, the ecosystem contains a rich set of development tools for writing, debugging, and publishing Python applications.

Some of the key advantages of Python:

- **Python is Interpreted:** Python is processed at runtime by the interpreter. You do not need to compile your program before executing it. This is similar to PERL and PHP.
- **Python is Interactive:** You can actually sit at a Python prompt and interact with the interpreter directly to write your programs.
- **Python is Object-Oriented:** Python supports Object-Oriented style or technique of programming that encapsulates code within objects.
- **Python is a Beginner's Language:** Python is a great language for the beginnerlevel programmers and supports the development of a wide range of applications from simple text processing to WWW browsers to games.

Features of Python

There are many features in Python, some of which are described below:



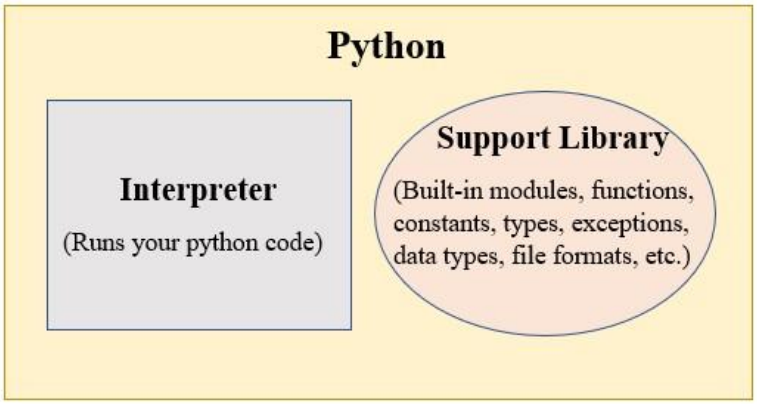
- **Readable:** Python is a very readable language.
- **Easy to Learn:** Learning python is easy as this is a expressive and high level programming language, which means it is easy to understand the language and thus easy to learn.
- **Cross platform:** Python is available and can run on various operating systems such as Mac, Windows, Linux, Unix etc. This makes it a cross platform and portable language.
- **Open Source:** Python is an open-source programming language.
- **Large standard library:** Python comes with a large standard library that has some handy codes and functions which we can use while writing code in Python.
- **Free:** Python is free to download and use. This means you can download it for free and use it in your application. Python is an example of a FLOSS (Free/Libre Open Source Software), which means you can freely distribute copies of this software, read its source code and modify it.
- **Supports exception handling:** If you are new, you may wonder what is an exception? An exception is an event that can occur during program exception and can disrupt the normal flow of program. Python supports exception handling which means we can write less error prone code and can test various scenarios that can cause an exception later on.
- **Advanced features:** Supports generators and list comprehensions. We will cover these features later.

- **Automatic memory management:** Python supports automatic memory management which means the memory is cleared and freed automatically. You do not have to bother clearing the memory.

How Python runs?

When the Python software is installed on your machine, minimally, it has:

- an interpreter
- a support library

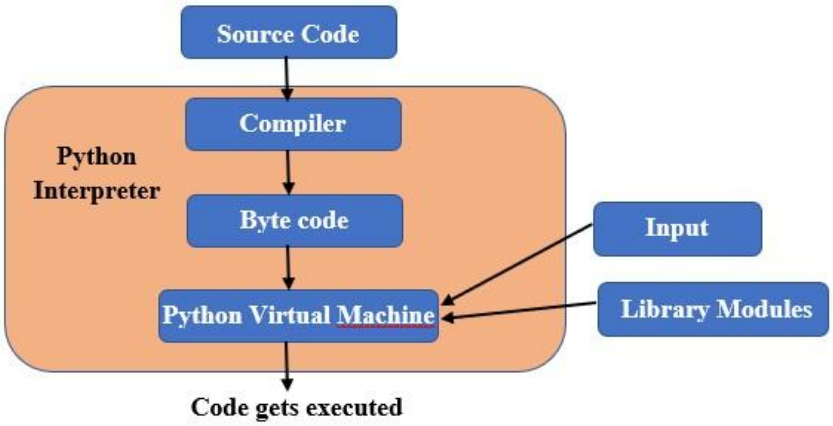


The Interpreter

Interpreter is nothing but a software which can run your Python scripts.
Interestingly, it can be implemented in any programming language!

- CPython is the default interpreter for Python which is written in C programming language.
- Jython is another popular implementation of python interpreter written using Java programming language.

Python's view of Interpreter:



The Python source code goes through the following to generate an executable code:

- Python source code or instruction will be read by the python compiler. Then it verifies that the instruction is well-formatted, that is, each line of the syntax will be checked. If it identifies an error, it immediately pauses the translation and shows an error message.
- If error is not found, i.e. if the python instruction or source code is well-formatted then it translates into its equivalent form in an intermediate language known as the "Byte code" by the compiler.
- Byte code is then sent to the Python Virtual Machine (PVM) which is the python interpreter. Now it converted to the python byte code into machine-executable code by the PVM. The conversion is halted with an error message while an error occurs during this interpretation.

5.2 Applications of Python

- **Web Applications:** Web framework like Django and Flask are based on Python. They help you write server side code which helps you manage database, write backend programming logic, mapping urls etc.
- **Machine Learning:** There are many machine learning applications written in Python. Machine learning is a way to write a logic so that a machine can learn and solve a particular problem on its own. For example, products recommendation in websites like Amazon, Flipkart, eBay etc. is a machine learning algorithm that recognizes user's interest. Face recognition and Voice recognition in your phone is another example of machine learning.
- **Data Analysis and Visualization:** The process of finding trends and correlations in our data by representing it pictorially is called Data Visualization. To perform data visualization in python, we can use various python data visualization modules such as Matplotlib, Seaborn, Plotly, and many other such data visualization packages with different features for creating informative, customized, and appealing plots to present data in the most simple and effective way.
- **Scripting:** Scripting is writing small programs to automate simple tasks such as sending automated response emails etc. Such type of applications can also be written in Python programming language.
- **Desktop applications:** We can develop desktop application in Python using library like TKinter or QT.

• **Game Development:** Python provides a built-in library called pygame, which used to develop the game. Once we understand the basic concepts of Python programming, we can use the pygame library to make games with attractive graphics, suitable animation, and sound. Pygame is a cross-platform library that is used to design video games.

• **Scientific and Numeric Computing:** There are numerous libraries available in Python for scientific and numeric computing. SciPy is a collection of packages for mathematics, science, and engineering. Pandas is a data analysis and modeling library. IPython is a powerful interactive shell that features easy editing and recording of a work session, and supports visualizations and parallel computing.

• **Desktop GUIs:** To create a desktop application, you need to learn the basics of Python, object-oriented programming, and the fundamentals of the Tkinter library. Tkinter is a GUI (Graphical User Interface) library of Python, which can help you create desktop apps easily.

5.3 Technologies Used:

Numpy :

NumPy is the fundamental package for scientific computing in Python. NumPy is a Python library used for working with arrays. It also has functions for working in domain of linear algebra, fourier transform, and matrices. NumPy was created in 2005 by Travis Oliphant. It is an open source project and we can use it freely.

Numerical Python:

It is a Python library that provides a multidimensional array object, various derived objects (such as masked arrays and matrices), and an assortment of routines for fast operations on arrays, including mathematical, logical, shape manipulation, sorting, selecting, I/O, discrete Fourier transforms, basic linear algebra, basic statistical operations, random simulation and much more.

At the core of the NumPy package, is the ndarray object. This encapsulates ndimensional arrays of homogeneous data types, with many operations being performed in compiled code for performance. There are several important differences between NumPy arrays and the standard Python sequences:

- NumPy arrays have a fixed size at creation, unlike Python lists (which can grow dynamically). Changing the size of an ndarray will create a new array and delete the original.
- The elements in a NumPy array are all required to be of the same data type, and thus will be the same size in memory. The exception: one can have arrays of (Python, including NumPy) objects, thereby allowing for arrays of different sized elements.
- NumPy arrays facilitate advanced mathematical and other types of operations on large numbers of data. Typically, such operations are executed more efficiently and with less code than is possible using Python's built-in sequences.
- A growing plethora of scientific and mathematical Python-based packages are using NumPy arrays; though these typically support Python-sequence input, they convert such input to NumPy arrays prior to processing, and they often output NumPy arrays. In other words, in order to efficiently use much (perhaps even most) of today's scientific/mathematical Python-based software, just knowing how to use Python's built-in sequence types is insufficient - one also needs to know how to use NumPy arrays.

Pandas :

Pandas is an open-source library that is made mainly for working with relational or labeled data both easily and intuitively. It provides various data structures and operations for manipulating numerical data and time series. This library is built on top of the NumPy library. Pandas is fast and it has high performance & productivity for users.

Data scientists make use of Pandas in Python for its following advantages:

- Easily handles missing data
- It uses Series for one-dimensional data structure and DataFrame for multidimensional data structure
- It provides an efficient way to slice the data
- It provides a flexible way to merge, concatenate or reshape the data
- It includes a powerful time series tool to work with

a nutshell, Pandas is a useful library in data analysis. It can be used to perform In data manipulation and analysis. Pandas provide powerful and easy-to-use data structures, as well as the means to quickly perform operations on these structures.

Matplotlib :

Matplotlib is a cross-platform, data visualization and graphical plotting library for Python and its numerical extension NumPy. As such, it offers a viable open source alternative to MATLAB. Developers can also use matplotlib's APIs (Application Programming Interfaces) to embed plots in GUI applications.

A Python matplotlib script is structured so that a few lines of code are all that is required in most instances to generate a visual data plot. The matplotlib scripting layer overlays two APIs:

- The pyplot API is a hierarchy of Python code objects topped by matplotlib.pyplot
- An OO (Object-Oriented) API collection of objects that can be assembled with greater flexibility than pyplot. This API provides direct access to Matplotlib's backend layers.

Matplotlib and Pyplot in Python

The pyplot API has a convenient MATLAB-style stateful interface. In fact, matplotlib was originally written as an open source alternative for MATLAB. The OO API and its interface is more customizable and powerful than pyplot, but considered more difficult to use. As a result, the pyplot interface is more commonly used, and is referred to by default in this article. Understanding matplotlib's pyplot API is key to understanding how to work with plots:

- **matplotlib.pyplot.figure:** Figure is the top-level container. It includes everything visualized in a plot including one or more Axes.
- **matplotlib.pyplot.axes:** Axes contain most of the elements in a plot: Axis, Tick, 7Line2D, Text, etc., and sets the coordinates. It is the area in which data is plotted. Axes include the X-Axis, Y-Axis, and possibly a Z-Axis, as well.

Sklearn scikit-learn is an open-source Python library that implements a range of machine learning, pre-processing, cross-validation, and visualization algorithms using a unified interface.

Important features of scikit-learn:

- Simple and efficient tools for data mining and data analysis. It features various classification, regression and clustering algorithms including support vector machines, random forests, gradient boosting, k-means, etc.
- Accessible to everybody and reusable in various contexts.
- Built on the top of NumPy, SciPy, and matplotlib. Open source, commercially usable – BSD license.

Before installing scikit-learn, ensure that you have NumPy and SciPy installed. Once you have a working installation of NumPy and SciPy, the easiest way to install scikit-learn is using pip:

pip install -U scikit-learn

Seaborn

Seaborn is a library for making statistical graphics in Python. It builds on top of matplotlib and integrates closely with pandas data structures.

Seaborn helps you explore and understand your data. Its plotting functions operate on data frames and arrays containing whole datasets and internally perform the necessary semantic mapping and statistical aggregation to produce informative plots.

5.4 Jupyter Notebook

The Jupyter Notebook is an open-source web application. In this juypter notebook users allowed to create and share documents that contains live code, equations, visualizations, and etc.

Uses include:

- Data transforming and cleaning
- Numerical reproduction
- Statistical modelling
- Data visualization is done
- Machine learning, and many more.

Jupyter Notebook App

An interactive Jupyter Notebook App is a client-server application which grant users to editing and running code interactively and notebook documents through a web browser. It can be executed without requiring internet access on a local desktop.

Kernels:

A notebook kernel is a "computational engine" which executes the code consisting in a Notebook document. The associated kernel is launched automatically when notebook document is opened by you.

Notebook Dashboard

When you launch Jupyter Notebook App, the Notebook Dashboard is the component which will be shown first. It is mainly used to open notebook documents, and to maintain the running kernels (visualization and shutdown). It has some more features similar to a file manager, namely navigating folders and renaming/deleting files.

CHAPTER-6. SAMPLE CODE

```
from matplotlib import pyplot as plt

from matplotlib import image

import numpy as np

import cv2

import mediapipe as mp

joint_list = [[8,7,6,5], [12,11,10,9], [16,15,14,13], [20,19,18,17]]

def draw_finger_angles(image, results, joint_list):

    for hand in results.multi_hand_landmarks:

        for joint in joint_list:

            a = np.array([hand.landmark[joint[0]].x, hand.landmark[joint[0]].y])

            b = np.array([hand.landmark[joint[1]].x, hand.landmark[joint[1]].y])

            c = np.array([hand.landmark[joint[2]].x, hand.landmark[joint[2]].y])

            d = np.array([hand.landmark[joint[3]].x, hand.landmark[joint[3]].y])

            radians_1 = np.arctan2(c[1] - b[1], c[0]-b[0]) - np.arctan2(a[1]-b[1], a[0]-b[0])

            angle_1 = np.abs(radians_1*180.0/np.pi)

            radians_2 = np.arctan2(d[1] - c[1], d[0]-c[0]) - np.arctan2(b[1]-c[1], b[0]-c[0])

            angle_2 = np.abs(radians_2*180.0/np.pi)

            if angle_1 > 180.0:

                angle_1 = 360-angle_2

            if angle_2 > 180.0:
```

```
            angle_2 = 360-angle_2
        if angle_1<175:
                cv2.putText(image, str(round(angle_1, 2)), tuple(np.multiply(b,
[image.shape[1], image.shape[0]]).astype(int)),
                  cv2.FONT_HERSHEY_SIMPLEX, 0.5, (0, 0, 255), 1, cv2.LINE_AA)
        else:
            cv2.putText(image, str(round(angle_1, 2)), tuple(np.multiply(b,
[image.shape[1], image.shape[0]]).astype(int)),
                  cv2.FONT_HERSHEY_SIMPLEX, 0.5, (0, 255, 0), 1, cv2.LINE_AA)
        if angle_2<175:
                cv2.putText(image, str(round(angle_2, 2)), tuple(np.multiply(c,
[image.shape[1], image.shape[0]]).astype(int)),
                  cv2.FONT_HERSHEY_SIMPLEX, 0.5, (0, 0, 255), 1, cv2.LINE_AA)
        else:
            cv2.putText(image, str(round(angle_2, 2)), tuple(np.multiply(c,
[image.shape[1], image.shape[0]]).astype(int)),
                  cv2.FONT_HERSHEY_SIMPLEX, 0.5, (0, 255, 0), 1, cv2.LINE_AA)
    return image
```

CHAPTER-7. TESTING

7.1 Introduction

The testing phase in rheumatoid arthritis detection using image processing is an essential part of the project as it determines the accuracy and reliability of the system. The testing phase involves evaluating the performance of the system using various datasets and analyzing the results obtained. The testing is carried out using two different approaches, including quantitative and qualitative evaluations.

In quantitative evaluation, various statistical measures are used to assess the performance of the system, such as accuracy, sensitivity, specificity, and precision. On the other hand, qualitative evaluation involves a visual inspection of the system's output and determining if the results obtained are consistent with the expected results. Overall, the testing phase is crucial in ensuring that the system is functioning as intended and providing accurate results for the detection of rheumatoid arthritis

.System testing and implementation

System testing and implementation are crucial parts of any software development project. In the case of rheumatoid arthritis detection using image processing, these stages involve ensuring that the software meets the functional and non-functional requirements that were established during the design phase.

During system testing, the software is tested as a whole to ensure that it functions as intended. This involves conducting a series of tests to evaluate the system's performance, accuracy, and reliability. The system is tested with different datasets to ensure that it is robust and can handle variations in input data. Once the system has been thoroughly tested and all bugs have been resolved, it is ready for implementation.

Implementation involves deploying the software in a real-world environment and making it available for use by end-users. This involves installing the software on appropriate hardware, configuring it to work with the target systems, and providing training and support to end-users. The success of the implementation phase is measured by the system's ability to meet the requirements of end-users, as well as the system's reliability and performance in a real-world setting.

Testing techniques

There are several testing techniques that can be used for rheumatoid arthritis detection using image processing:

1. **Functional Testing:** This technique involves testing the software functionality by feeding it various inputs and analyzing the outputs. In this case, the system can be tested by providing it with different images of hand joints and checking whether it can detect and classify the images accurately.
2. **Performance Testing:** This technique involves testing the software performance in terms of speed, accuracy, and response time. In this case, the system can be tested by providing it with a large number of images of hand joints and measuring the time taken by the system to detect and classify the images.
3. **Integration Testing:** This technique involves testing the software modules or components when integrated together. In this case, the system can be tested by integrating the image processing module with the machine learning module and testing the entire system's functionality.
4. **User Acceptance Testing:** This technique involves testing the software from the end-user's perspective. In this case, the system can be tested by providing it to a group of users who can provide feedback on the system's usability, accuracy, and overall performance.

Testing Strategies

Unit testing

Unit testing involves the design of test cases that validate that the internal program logic is functioning properly and that program inputs produce valid outputs. All decision branches and internal code flow should be validated. It is the testing of individual software units of the application .it is done after the completion of an individual unit before integration. This is structural testing, that relies on knowledge of its construction and is invasive. Unit tests perform basic tests at the component level and test a specific business process, application, and/or system configuration. Unit tests ensure that each unique path of a business process performs accurately to the documented specifications and contains clearly defined inputs and expected results.

This system consists of 3 modules. These are the Reputation module, route discovery module, and audit module. Each module is taken as a unit and tested. Identified errors are corrected and executable units are obtained.

Integration testing

Integration tests are designed to test integrated software components to determine if they run as one program. Testing is event-driven and is more concerned with the basic outcome of screens or fields. Integration tests demonstrate that although the components were individually satisfied, as shown by successful unit testing, the combination of components is correct and consistent. Integration testing is specifically aimed at exposing the problems that arise from the combination of components.

System Testing

System testing ensures that the entire integrated software system meets requirements. It tests a configuration to ensure known and predictable results. An example of system testing is the configuration-oriented system integration test. System testing is based on process descriptions and flows, emphasizing pre-driven process links and integration points.

7.2 Sample Test Case Specification:

Test Number	Test Case	Output	Result
T1	Open project in Jupyter Notebook	Project loads successfully	Pass
		Project doesn't loads successfully	Fail
T2	Run the main file	Program is executing successfully	Pass
		Program isn't executing successfully.	Fail
T3	Data loading function is executed	Data loads successfully	Pass
		Data doesn't loads successfully	Fail
T4	Data balancing function is called	Data splits in equal portion as train data and test data	Pass
		Data doesn't split in equal portion as train data and test data	Fail
T5	Feature extraction is performed	Extracts features from the data correctly	Pass
		Features aren't extracted from the data	Fail
T6	Prediction model is called	Results are estimated for Sales Forecasting	Pass
		Results are not estimated for Sales Forecasting	Fail
T7	Error rate is derived from the function	Error rate is measured and displayed	Pass
		Error rate is not measured and not displayed	Fail

7.3 Test Case Screens:

Test case 1:

Fig 7.3.1 input

Test case 2:

Fig 7.3.2 input

CHAPTER-8.SCREENSHOTS

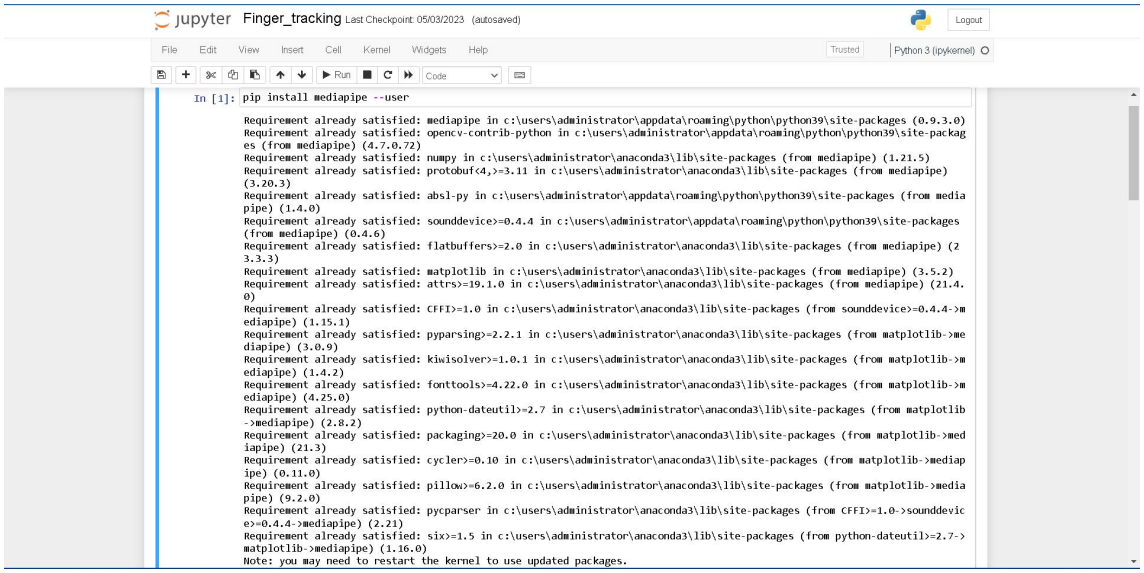


Fig 8.1 installing the required library

Description: The command "pip install mediapipe --user" is a terminal command used to install the mediapipe Python package.

- "pip" is a package installer for Python.
- "install" is a command used to install a package.
- "mediapipe" is the name of the package being installed.

When executed, this command will download and install the mediapipe package along with its dependencies on the user's local machine, allowing the user to access the mediapipe library in their Python scripts.

```
Requirement already satisfied: six>=1.5 in c:\users\administrator\anaconda3\lib\site-packages (from python-dateutil>=2.7->
matplotlib->mediapipe) (1.16.0)
Note: you may need to restart the kernel to use updated packages.

In [2]: from matplotlib import pyplot as plt
        from matplotlib import image
        import numpy as np

        import cv2
        import mediapipe as mp

In [3]: joint_list = [[8,7,6,5], [12,11,10,9], [16,15,14,13], [20,19,18,17]]
```

Fig 8.2 Importing the requirements

Description: The above lines of code import necessary libraries for image processing and analysis in Python. `matplotlib.pyplot` and `matplotlib.image` are imported as `plt` and `image`, respectively, to visualize and read in images. `numpy` is imported as `np` to manipulate and perform operations on arrays. `cv2` is imported from OpenCVlibrary, which is used for computer vision tasks such as image processing, object detection, and feature detection. `mediapipe` library is imported as `mp`, which is a popular framework used for building machine learning models for media such as images and video.

```
In [4]: def draw_finger_angles(image, results, joint_list):
            # Loop through hands
            for hand in results.multi_hand_landmarks:
                #Loop through joint sets
                for joint in joint_list:
                    a = np.array([hand.landmark[joint[0]].x, hand.landmark[joint[0]].y]) # First coord
                    b = np.array([hand.landmark[joint[1]].x, hand.landmark[joint[1]].y]) # Second coord
                    c = np.array([hand.landmark[joint[2]].x, hand.landmark[joint[2]].y]) # Third coord
                    d = np.array([hand.landmark[joint[3]].x, hand.landmark[joint[3]].y]) #fourth coord

                    radians_1 = np.arctan2(c[1] - b[1], c[0]-b[0]) - np.arctan2(a[1]-b[1], a[0]-b[0])
                    angle_1 = np.abs(radians_1*180.0/np.pi)
                    radians_2 = np.arctan2(d[1] - c[1], d[0]-c[0]) - np.arctan2(b[1]-c[1], b[0]-c[0])
                    angle_2 = np.abs(radians_2*180.0/np.pi)

                    if angle_1 > 180.0:
                        angle_1 = 360-angle_1

                    if angle_2 > 180.0:
                        angle_2 = 360-angle_2

                    if angle_1<175:
                            cv2.putText(image, str(round(angle_1, 2)), tuple(np.multiply(b, [image.shape[1], image.shape[0]]).astyp
                                cv2.FONT_HERSHEY_SIMPLEX, 0.5, (0, 0, 255), 1, cv2.LINE_AA)
                    else:
                        cv2.putText(image, str(round(angle_1, 2)), tuple(np.multiply(b, [image.shape[1], image.shape[0]]).astype(in
                                cv2.FONT_HERSHEY_SIMPLEX, 0.5, (0, 255, 0), 1, cv2.LINE_AA)
                    if angle_2<175:
                            cv2.putText(image, str(round(angle_2, 2)), tuple(np.multiply(c, [image.shape[1], image.shape[0]]).astyp
                                cv2.FONT_HERSHEY_SIMPLEX, 0.5, (0, 0, 255), 1, cv2.LINE_AA)
                    else:
                        cv2.putText(image, str(round(angle_2, 2)), tuple(np.multiply(c, [image.shape[1], image.shape[0]]).astype(in
                                cv2.FONT_HERSHEY_SIMPLEX, 0.5, (0, 255, 0), 1, cv2.LINE_AA)
```

Fig 8.3 calculating the angle between the joints

Description: The above code defines a function called "draw_finger_angles" that takes in an image, results, and a joint_list as inputs. This function is used to draw angles between finger joints detected by the MediaPipe Hand tracking library. The code loops through all detected hands and then through each joint set defined in the joint_list. It calculates the angle between the joints using arctan2 and the coordinates of each joint. It then uses this angle to draw text on the image at the midpoint of the angle, indicating the angle value. If the angle is less than 175 degrees, the text is drawn in red, and if greater than 175 degrees, it is drawn in green. Finally, the modified image is returned.

mp_hands = mp.solutions.hands

# For static images:
mp_model = mp_hands.Hands(
    static_image_mode=True, # only static images
    max_num_hands=2, # max 2 hands detection
    min_detection_confidence=0.5) # detection confidence

image = cv2.imread("RHEUMATOID/11.jpg")

image = cv2.flip(image, 1)

results = mp_model.process(cv2.cvtColor(image, cv2.COLOR_BGR2RGB))

# Detections
# print(results)
# print(results.multi_handedness)

image_height, image_width, _ = image.shape
annotated_image = image.copy()
for hand_landmarks in results.multi_hand_landmarks:
    print('hand_landmarks:', hand_landmarks)
    print(
      f'Index finger tip coordinates: (',
      f'{hand_landmarks.landmark[mp_hands.HandLandmark.INDEX_FINGER_TIP].x * image_width}, '
      f'{hand_landmarks.landmark[mp_hands.HandLandmark.INDEX_FINGER_TIP].y * image_height})'
    )
```

Fig 8.4 checking the angle is normal or abnormal

Description: The above code uses the MediaPipe library to detect and track hands in an image. It first initializes the MediaPipe Hands model to process static images, sets the maximum number of hands to detect as two, and specifies a minimum detection confidence. It then reads an image and flips it horizontally. The model processes the image, and the landmarks of the detected hands are extracted and printed to the console. The landmarks are then used to draw connections between them, which are visualized on the image. Finally, the function `draw_finger_angles()` is called to draw the angles of finger joints to the image. The resulting image is displayed, and the program waits for the user to press a key before exiting.

CONCLUSION

The detection of rheumatoid arthritis using joint angle calculation appears to be a promising approach. Studies have shown that measuring joint angles can accurately assess the severity of joint deformities caused by rheumatoid arthritis and can potentially aid in the diagnosis and treatment of the disease. This method has the advantage of being non-invasive and can provide clinicians with valuable information about the progression of the disease. However, it should be noted that joint angle measurement alone may not be sufficient for diagnosis, and additional clinical and imaging tests may be necessary. Overall, joint angle calculation is a valuable tool that can aid in the diagnosis and management of rheumatoid arthritis.
